

Composite Wild Bird Indicators (WBI) are „sold“ as indicators to measure (examples):

- Farmland biodiversity (R. Gregory, EBCC presentation 2006)
- Progress towards the target to achieve a significant reduction in the rate of biodiversity loss (Butchart et al. 2010, Science 328: 1164-1168)
- Environmental health (Gregory & van Strien 2010, Ornithol. Sci. 9)
- Structural and sustainable development (Butler et al. 2010, Agricult., Ecosyst. & Environm. 137: 348-357)
- Implementation and success of agri-environmental schemes (Butler et al. 2010, Agricult., Ecosyst. & Environm. 137: 348-357)

Do they?

Three different examples of composite Wild Bird Indicators:

- suggestive messages
- implications
- the (possible) „truth“ behind

German Farmland Bird Indicator

German Farmland Bird Indicator

Indicator goes down ↓

Suggestive message:

- > Birds are declining.
- > Biodiversity is declining
- > Situation on farmland is bad (not sustainable).

Conservation & policy implications:

- > Policy target of halting biodiversity loss is not achieved.
- > Conservation efforts have to be improved/ increased.
- > Agricultural policy is not sustainable / should be changed.

Possible „truth“ behind:

- > A substantial proportion of indicator species must be on decline.
- > If there occur any increases at all, they are weaker / less frequent than declines.

→ Messages and implications OK

German Forest Birds Indicator

German Forest Birds Indicator

Indicator is stable/fluctuating →

Suggestive message:

- > Situation of forest birds is fairly stable / OK.
- > Status of biodiversity is +/- stable.

Conservation & policy implications:

- > Policy target of halting biodiversity loss is achieved.
- > No serious conservation problem.
- > Current land use policy is acceptable / at least not disadvantageous for birds/biodiversity.

Possible „truth“ behind:

- > A substantial proportion of species is delining.
- > Declines are masked by increases of other species.
- > If development continues we will have a substantial loss of biodiversity.
- > We have a serious conservation problem.
- > There is a need of policy change

→ Indicator can be misleading

German Wetland Birds Indicator

German Wetland Birds Indicator

Indicator goes up ↑

Suggestive message:

- > Situation of wetland birds is improving.
- > Status of biodiversity is improving.

Conservation & policy implications:

- > Policy target of halting biodiversity loss is achieved.
- > Conservation efforts have been successful.
- > Current policy is sustainable & supports biodiversity.

Possible „truth“ behind:

- > A substantial proportion of species is delining.
- > Declines are over-compensated by increasing species.
- > Increasing species are more numerous or increases are stronger than declines (e.g. some species benefit, some suffer from eutrophication).
- > We have a serious conservation problem.
- > There is a need of policy change

→ Indicator can be misleading

Example of selected German farmland bird indices

German Farmland Birds Indicator

Example: 3 declining and 2 increasing species

Example: 3 declining and 2 increasing species

Example: 3 declining and 2 increasing species

= OK

= loss of biodiversity!

What do composite Wild Bird Indicators (WBI) really measure? Which features or processes are indicated?

„The Farmland Bird Indicator is not the average of a mixture of positive and negative signals, but is meant to estimate one underlying signal using species trends as replicates“ (Arco van Strien in lit., 2010)

But what kind of signal is intended to be measured?

- Biodiversity or biodiversity loss? - **Not necessarily.**
- Environmental health? - **No.**
- Stability? - **No.**
- Sustainability? - **No.**
- Policy success? - **Not at all.**

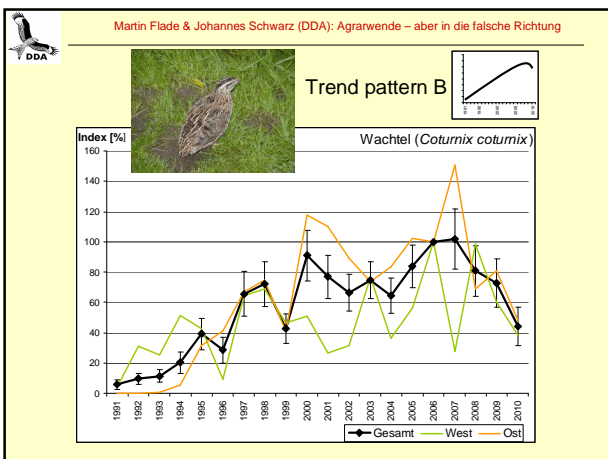

But what else?

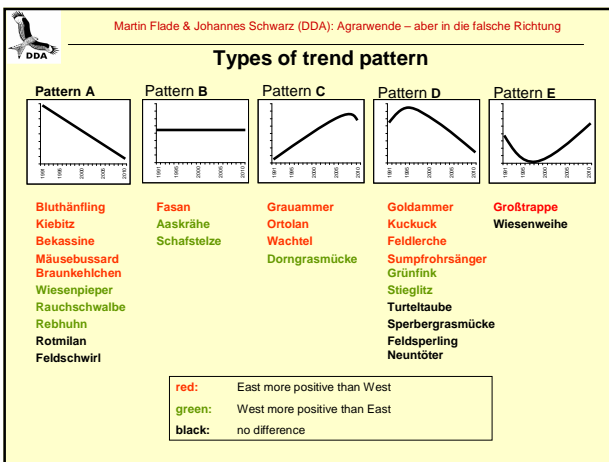

What is the „true message“ of WBI?

⇒ **But what to do now?**

1. Species groups with similar trend pattern

2. Five-years-declines and -increases approach

Proposal: measure 5-years-declines

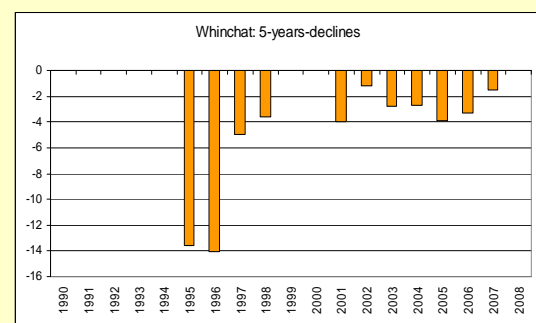

Proposal: measure 5-years-declines

5-years-declines: example of Whinchat

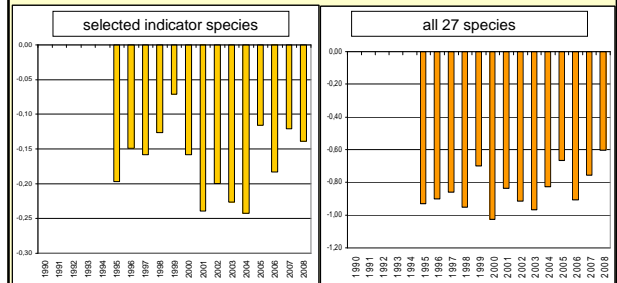

5-years-declines: example of Whinchat

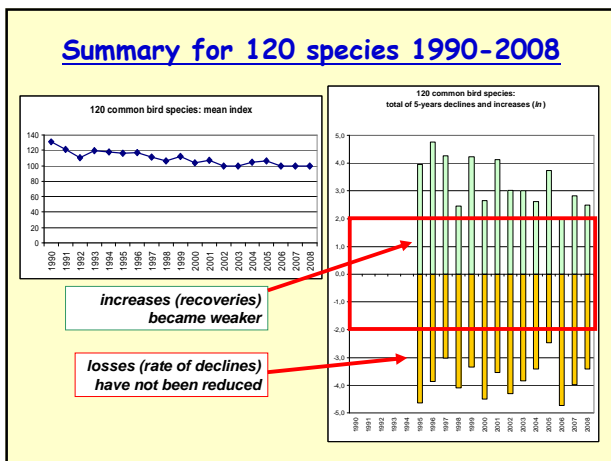

Attention! - for example: decline by 20 % per year

Idea for an indicator for biodiversity loss: total 5-years-declines in German farmland birds

⇒ losses continue / do slightly improve

Advantages of the proposed indicator:

- ⇒ measures declines/losses and increases separately
- ⇒ can include as many species as possible (no need of species selection)
- ⇒ measures reality against policy targets (whether loss of biodiversity has continued, slowed down or halted)
- ⇒ increases do not mask declines
- ⇒ data-based target ranges (instead of agreement)

Disadvantages:

- ⇒ more difficult to understand (*but also: not so kryptic!*)
- ⇒ looks not so nice
- ⇒ increasing and declining species may exchange over time

Many thanks to

Christoph Sudfeldt (DDA), Arco van Strien

Dan Chamberlain, Marilise Wolf-Crowther

for fruitful discussions, and

>500 volunteers for providing the data
